Relational Data Model	6
Sample Data	7
SQL Examples	8
Constraint Enforcement	9
Conclusion	10

## **Project Description**

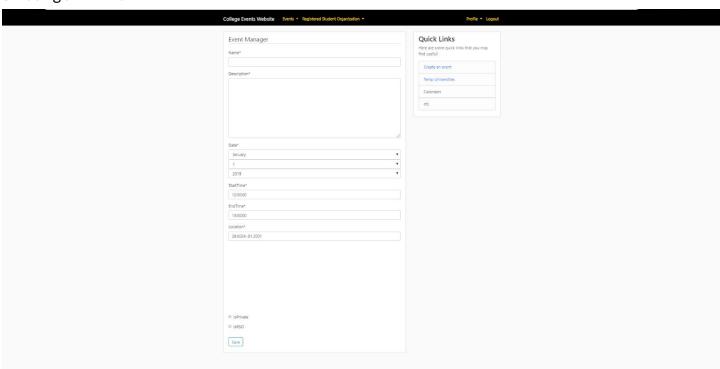

We have created a web application using the Django framework with a sqlite3 database. It allows users to create accounts of varying authority levels: student, admin, super admin, and then use those accounts based on the permissions they have to create or join registered student organizations (RSOs). Admins are able to create events with location and any user who has access to the event may add, edit, or delete their own comments.

## **GUI**

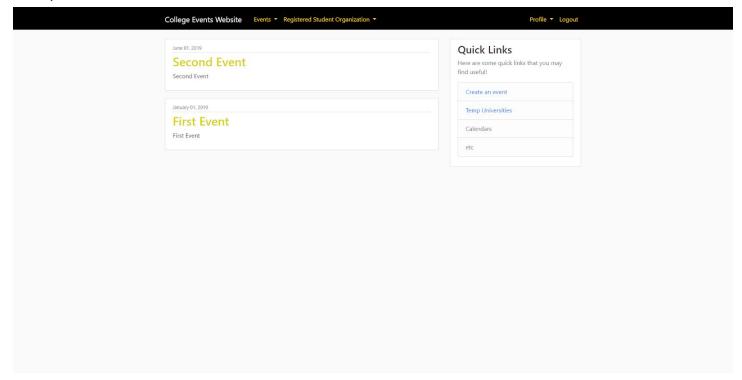

#### List of events

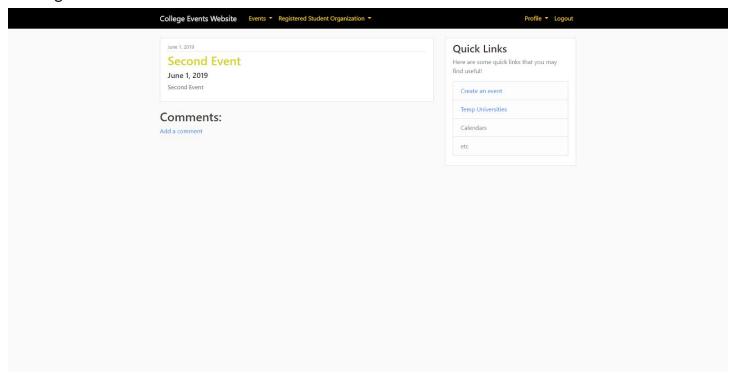

## Creating an event

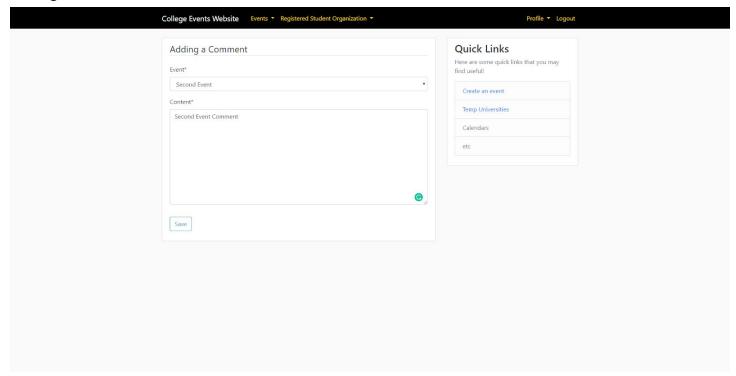

### The updated list of events

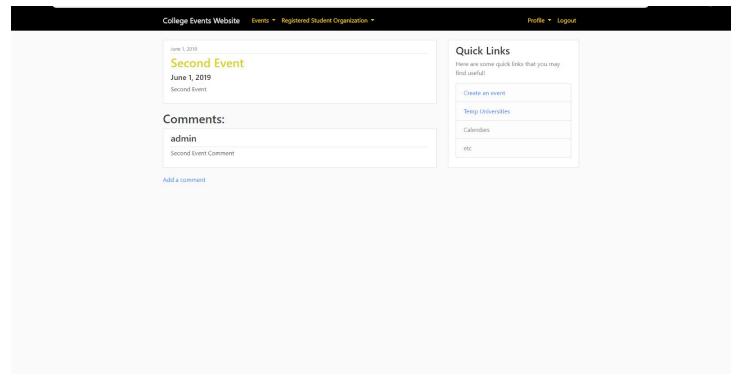

### Viewing an event

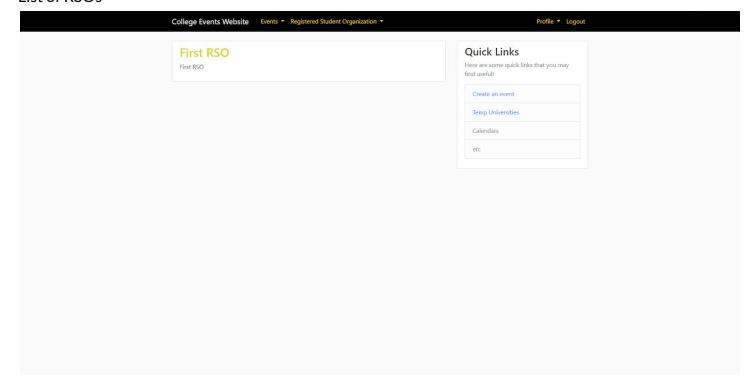

### Adding a comment to the event

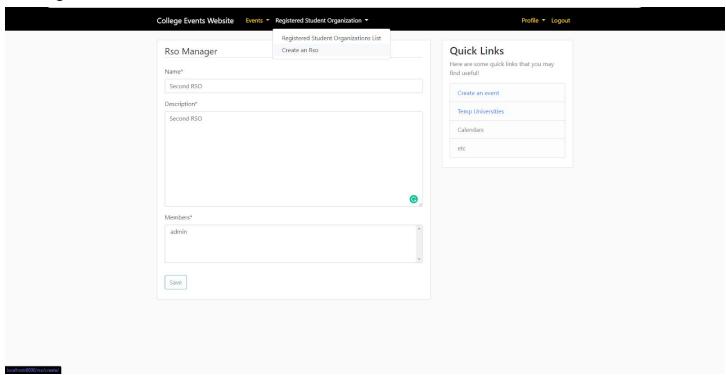

## Viewing the new comment

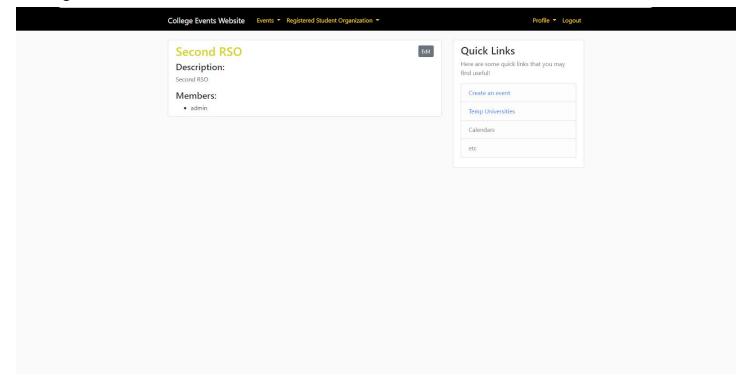

#### List of RSOs

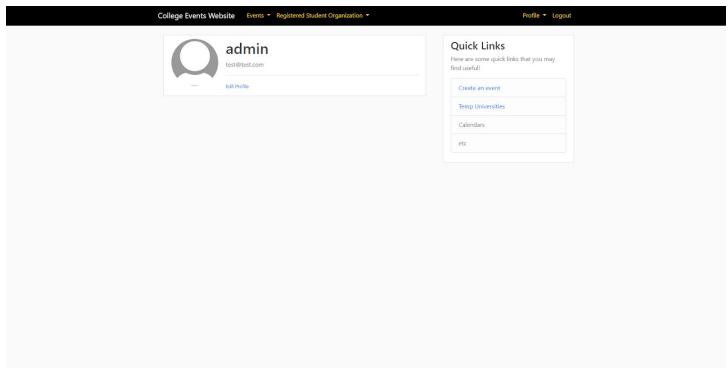

### Creating an RSO

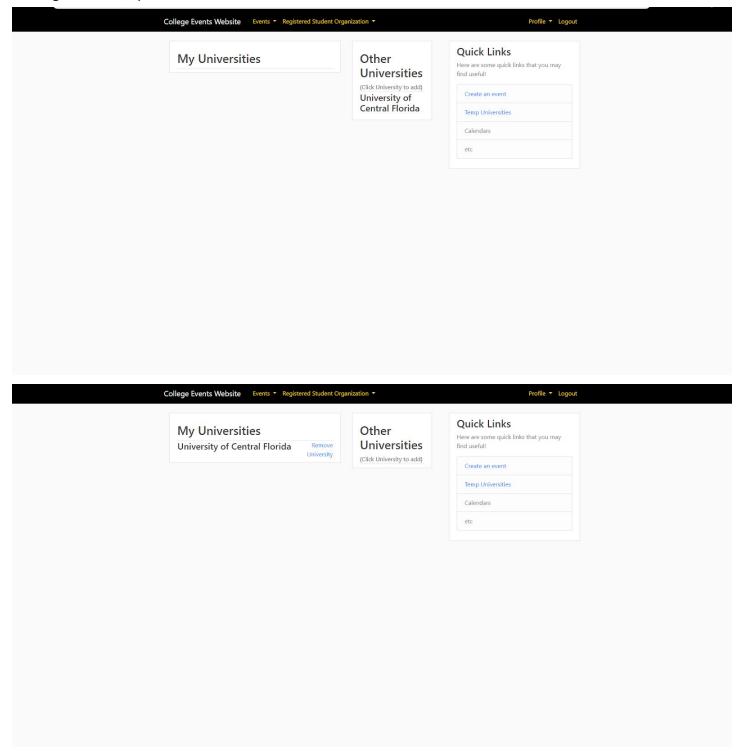

### Viewing the new RSO

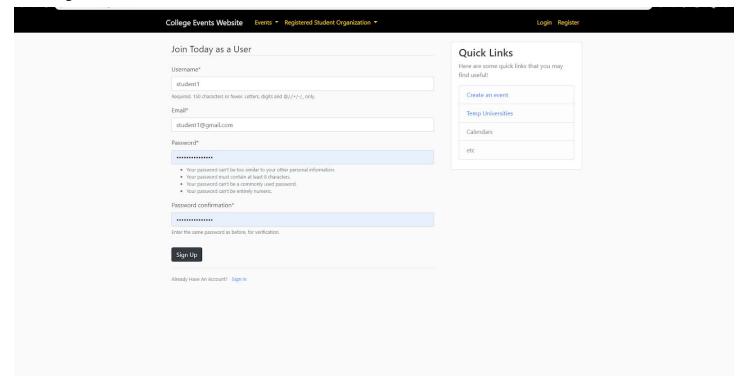

## Profile Page

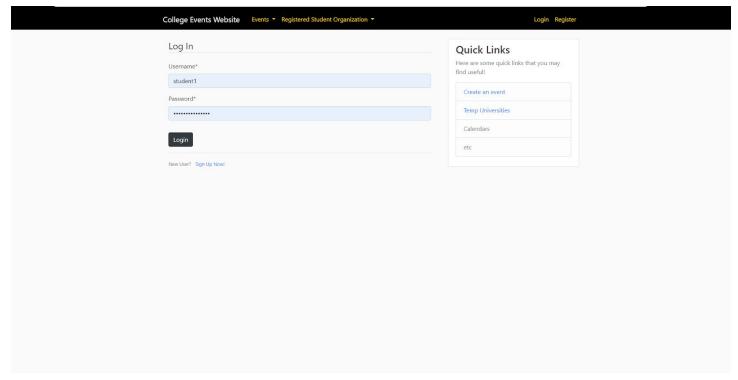

### Joining a university

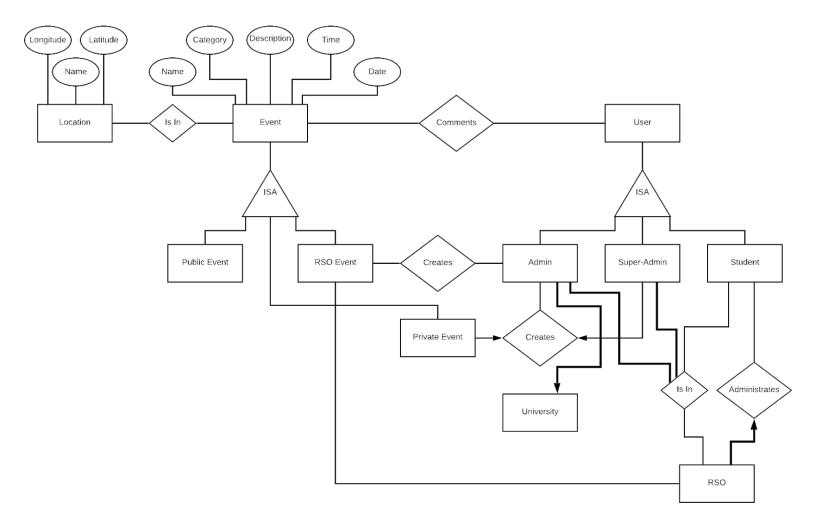

#### Creating a new user

#### Login page

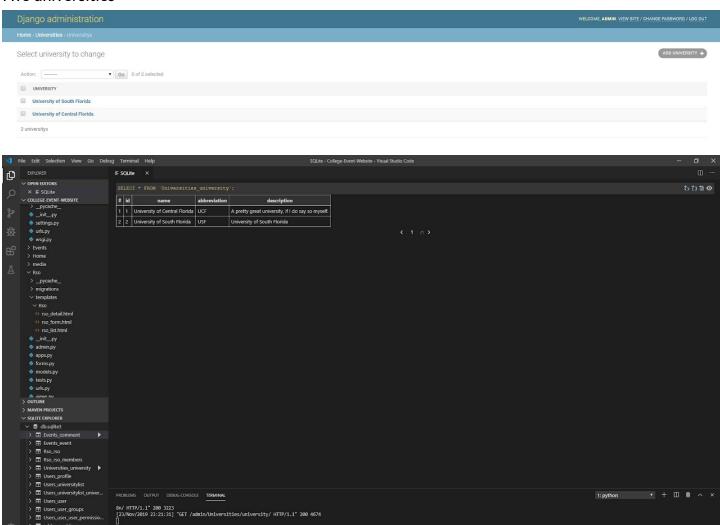

## **ER-Model**

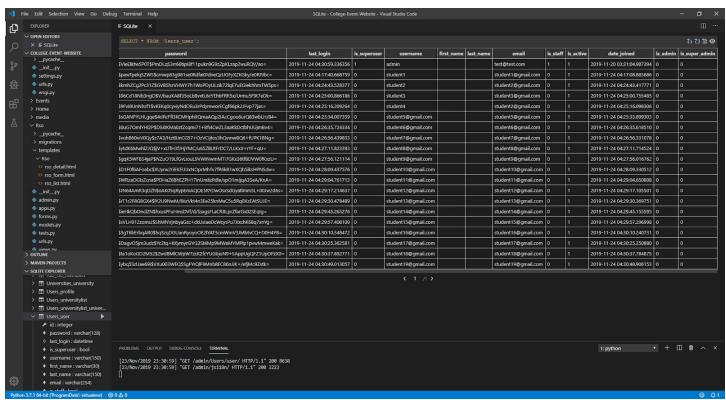

## Sample Data

#### Two universities

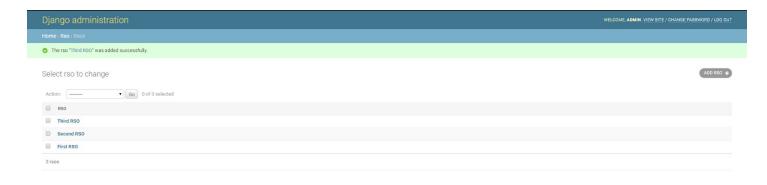

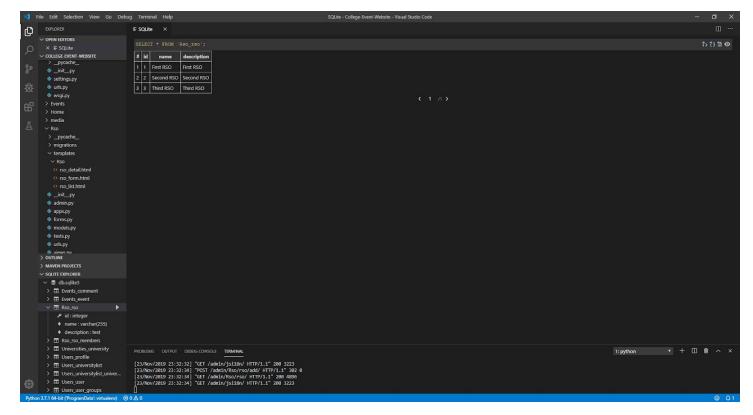

#### 20 users

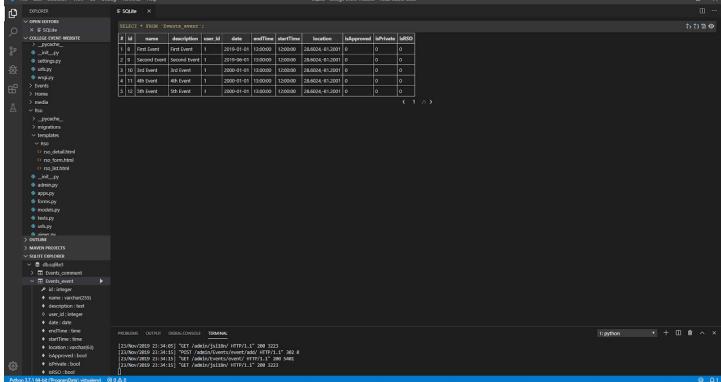

#### 3 RSOs

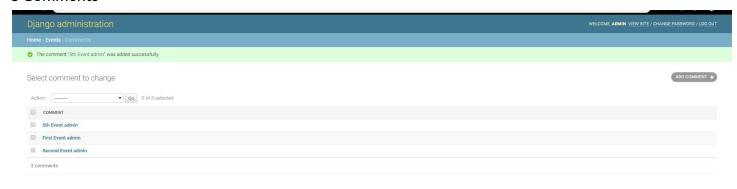

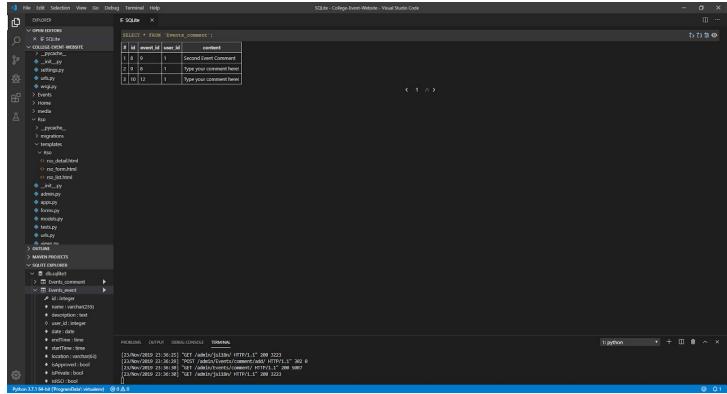

#### 5 Events

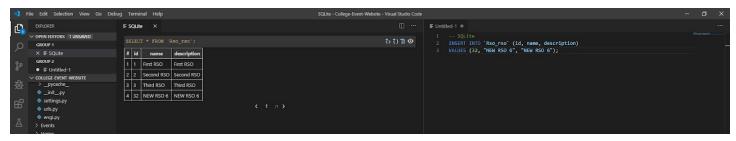

#### 3 Comments

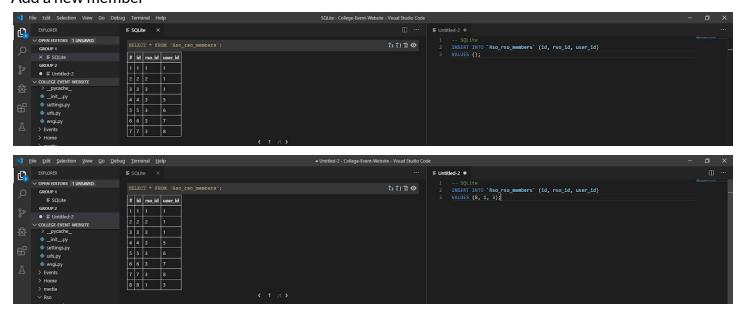

## **SQL** Examples

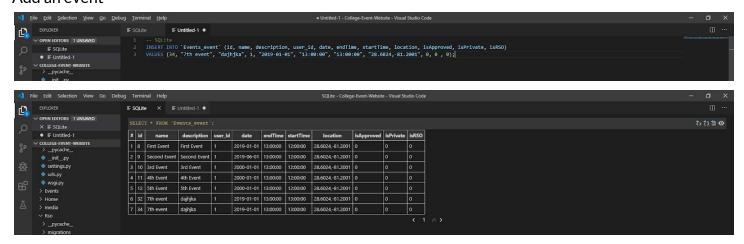

#### Add an RSO

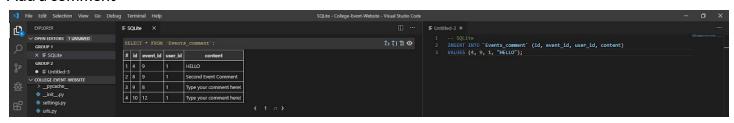

#### Add a new member

#### Add an event

#### Add a comment

## Conclusion

Our database under small loads such as what we are using currently is at a speed that is acceptable for moderate usage. Indexes that could be stand to improved are maybe using the address, university or location to sort users. Generally, you only want users from the same location or university so indexing based on that may speed up queries. Some improved functionality we would like to see in our application may be images for each event and RSO. Maybe we could integrate the UCF login or query the UCF API so that the database could be prefilled with student accounts.
